Abstract
This study aimed to compare biochemical vs. molecular methods for identification of Lactic Acid Bacteria (LAB) isolated from camel milk. Ten strains among 62 LAB isolates were chosen for identification using API50CHL and 16S rDNA sequencing. Only Gram-positive and catalase-negative isolates were considered. Citrate utilization, in the presence of carbohydrates, was studied. These strains were tested from the growth in NaCl (4, 6.5%), growth at different temperature (10-45°C) and growth at different pH values (4.2, 9.6). Results indicated that ten (10) strains were identified as: Lactococcus lactis, Lactobacillus pentosus, Lactobacillus plantarum, Lactobacillus brevis and Pediococcus pentosaceus by using biochemical method. However by molecular methods, all strains were identified as Enterococcus faecium. It was, thereby, concluded that each technique had its limitations but the molecular analysis is the most reliable.

Keywords: Biochemical identification; Molecular identification; Lactic acid bacteria

Introduction
In arid regions, camel milk is considered as one of the most important source of dairy products for human diet with potential therapeutic effects. Recent studies showed that camel milk is a natural source for probiotics (Al-Otaibi et al., 2013). The dominant and beneficial microflora in camel milk represented by LAB is a potential source of biological materials to be used in dairy technology (Khedid et al., 2009). LAB strains are characterized by their ability to transform lactose, to improve the digestibility (Weinberg et al., 2007) and to preserve fermented dairy products (Abdelbasset and Djamila, 2008). They were also employed for improvement of the taste, texture and viscosity in the manufacture of dairy products (Abdelbasset and Djamila, 2008). They were also employed for improvement of the taste, texture and viscosity in the manufacture of dairy products (Abdelbasset and Djamila, 2008). They were also employed for improvement of the taste, texture and viscosity in the manufacture of dairy products (Abdelbasset and Djamila, 2008).

Nutritional and growth requirements, biochemical-based methodologies for identification might not be conclusive in many cases. The conventional microbiological methods for bacterial identification are based on morphological and physiological characteristics such as Gram staining, cell shape, spore formation, enzyme production and the fermentation of different carbohydrates (Moraes et al., 2013). Phenotypic identification and biochemical tests have been considered for a long time the conventional procedure for routine identification of bacteria. Several methods have been developed in the last few years and many commercial multi-test kits such as the analytical profile index (API) test kits are widely used.

Recently, new molecular tools have been applied for the routine identification of microbes, and had led to an increase in the number of identified bacteria (Gevers and Coenye, 2007; Liu and Stahl, 2007; Bittar and Rolain, 2010). Most of the advance molecular methods are based on 16S ribosomal DNA sequences, complete or partial genomes (Ben Amour et al., 2007). Although molecular approaches remain the standard techniques for bacterial identification that have been proved to be very sensitive, they have some
limitations. The limits of these advanced techniques has been questioned due to the extent of their database, the need for complex procedures, trained personnel, specialized and expensive, equipment.

Considering the available techniques for identifying LAB, the objective of this study was to compare molecular and phenotypic methods for identifying LAB isolates: API50CHL and 16S rDNA sequencing.

MATERIAL AND METHODS

Sampling
Milk samples were collected from camels (Camelus dromedarius) belonging to the herd of the Arid lands Institute (IRA Medenine). The samples were immediately cooled (4°C) and brought to the laboratory in an isotherm containers and were analyzed immediately thereafter.

Bacterial isolation and characterization
LAB were isolated on Man-Rogosa-Sharp (MRS) (Pronadisa, Madrid, Spain) agar and incubated at 30°C for 24 to 48 h in order to apply the conventional tests for identification (Nguyen et al., 2007; Kopermsub and Yunchalard, 2010). All isolates were initially examined for Gram staining and catalase production. Only Gram-positive and catalase-negative isolates were considered. Citrate utilization, in the presence of carbohydrates, was studied on Simmons citrate medium (Fluka Biochemica). The presence of a blue coloration (even only locally on the surface) indicated a positive reaction. These strains were tested from the growth in NaCl (4, 6.5%), growth at different temperatures (10, 39 and 45 °C) at different salt concentrations were not observed. All strains grew at 45 °C and tolerate salinity 6.5%
did not grew under these conditions (Axelsson et al., 1998).

Indeed, lactococci or Enterococcus grew at 45 °C and tolerate salinity 6.5% and a pH of 9.6, while lactococci did not grow under these conditions (Axelsson et al., 1998).

Biochemical methods
Fermentation of carbohydrates was determined using API 50 CHL, a standardized system, consisting of 50 biochemical tests for the study of carbohydrate metabolism by microorganisms. API 50 CH was used in conjunction with API 50 CHL medium for the identification of Lactobacillus and related genera strips according to the manufacturer’s instructions (Biomerieux, Marcy l’Etoile, France) (Ghanbari et al., 2009). Briefly, 10 ml of pure water was dispensed with the strip placed in the incubation box, after the bacterial cultures had been introduced into the API 50 CHL system in API 50 CHL medium (5 ml). The set-up system was then incubated at appropriate temperature of 30°C for 24 and 48 h, after the wells were filled with the bacterial suspensions by the line mark with the addition of paraffin oil. Identification tables were prepared as (+/-) according to colour change in evaluation of results of API strips reaction. Numerical profiles of strains were identified adding positive values in indicative table. The API LAB PLUS database (Bio Merieux, France) was used for the interpretation of the results.

Molecular method
The genomic DNA of ten strains was extracted using the DNA extraction and purification kit according to the manufacturer instructions (Fermentas, UK). The PCR reaction mixture contained 0.5 μL of template DNA, 2.5 μL of reverse primer (10 mM), 2.5 μL of forward primer (10 mM), 2 μL of dNTP (25 mM), 4 μL of MgCl2 (25 mM), 5 μL of PCR buffer (10X) and 1 μL Taq polymerase, in a 50 μL final volume. The primers sequences used were S1 (5’AGAGTTTAGTAC (A,C) TGGCTCAG 3’) and S2 (5’ GG (A,C) TAMACCA (T,C) TTC 3’) for an 400 bp expected product size. The cycling program was 94 °C for 3 min, 29 cycles at 94 °C for 40 sec, 55 °C for 50 sec and 72 °C for 2 min. Sequencing of PCR product was made by the sequencing facility offered by Eurofins (Germany). The obtained nucleotide sequences, displayed by BioEdit software, were analyzed using the blast tool of the NCBI site in order to research identity percentages with the sequences present in databases (http://blast.ncbi.nlm.nih.gov/Blast.cgi).

RESULTS AND DISCUSSION

Isolation of lactic acid bacteria
A total of 62 strains were isolated from MRS agar. All of them grew at 37 °C under anaerobic conditions, were Gram positive, non-motile and catalase negative as preliminary characteristics. Only 29 of them were citrate positive. In microscopy, the cells had different shapes cocobacilli, cocci and bacilli, forming small chains of varying length, pairs or in clusters and were immobile. Only 10 strains were subjected to identification with biochemical and molecular methods. The ten strains encoded SCC1-2, SCC1-6, SCC1-7, SCC1-8, SCC1-13, SCC1-15, SCC1-24, SCC1-33, SLch6 and SLch14 are characterized by their ability to grow at different temperatures (10, 39 and 45 °C) at different salt concentrations (4, 6.5) while growth of these strains at 8% of salts concentration were not observed. All strains grew only at pH = 9.6 (Table 1). The strains of Gram-positive cocci form grouped in pairs or small chains represent the Lactococcus or Enterococcus. Furthermore, the distinction between the two kinds of Enterococcus and Lactococcus were affected upon growth tests at varying temperatures and at different concentrations of salts (4%, 8% and 6.5% NaCl). Indeed, enterococci grew at 45 °C and tolerate salinity 6.5% and a pH of 9.6, while lactococci did not grow under these conditions (Axelsson et al., 1998).

Biochemical identification of lactic strains
Ten strains chosen according to the difference in cell morphology were identified using API galleries. Regarding
the carbohydrates fermentations the strains were divided in two groups (Table 2). The first ones dominated by regular rods (SCC18, SCC17, SCC115, SCC12) which fermented mostly Amygdaline, Sorbitol, Esculine and Glycerol, were tentatively identified as L. plantarum, Lb. pentosus and Lb. brevis. The second group was coccoïd in shape (SLCh14, SLCh6, SCC113, SCC113, and SCC12). They fermented mostly, glycerol, esculine, amygdaline and amydon. They were tentatively identified as L. Lactis1 and Pediococcus pentosaceus. Earlier studies reported the presence of the Lactobacillus plantarum and lactobacillus brevis in Sudanese fermented camel milk (Ashmaig et al., 2009). Sun et al. (2010) isolated the Lactobacillus plantarum and Lactococcus lactis from traditional fermented milk in Mongolia.

Molecular phylogeny of the selected isolates

The selected strains (10 strains) were identified by partial sequencing of the gene coding for the 16S rRNA. The phylogenetic relationship of the experimental sequence and its close relatives were analyzed through the facilities of the Ribosomal Database Project (http://rdp.cme.msu.edu/). All the isolates were identified as Enterococcus faecium (Table 2). E. faecium was previously isolated from E. faecium, the carbohydrate-fermenting strains were divided into two groups (Table 2). The first one dominated by regular rods (SCC18, SCC17, SCC115, SCC12) which fermented mostly Amygdaline, Sorbitol, Esculine and Glycerol, were tentatively identified as L. plantarum, Lb. pentosus and Lb. brevis. The second group was coccoïd in shape (SLCh14, SLCh6, SCC113, SCC113, and SCC12). They fermented mostly, glycerol, esculine, amygdaline and amydon. They were tentatively identified as L. Lactis1 and Pediococcus pentosaceus. Earlier studies reported the presence of the Lactobacillus plantarum and lactobacillus brevis in Sudanese fermented camel milk (Ashmaig et al., 2009). Sun et al. (2010) isolated the Lactobacillus plantarum and Lactococcus lactis from traditional fermented milk in Mongolia.

Molecular phylogeny of the selected isolates

The selected strains (10 strains) were identified by partial sequencing of the gene coding for the 16S rRNA. The phylogenetic relationship of the experimental sequence and its close relatives were analyzed through the facilities of the Ribosomal Database Project (http://rdp.cme.msu.edu/). All the isolates were identified as Enterococcus faecium (Table 2). E. faecium was previously isolated from Egyptian camel milk (Hamed and Elaatar, 2013) and from Azerbaijani Motal cheese (Ahmadova et al., 2013; Akhmetzadykova et al., 2014). Enterococi, components of the human gastro-intestinal microbiota (Huycke et al., 1998), are very widespread in various raw food systems, especially of animal origin (Haji-Sfazi et al., 2011). They can be frequently associated to fermented foods (Franz et al., 2003) including cheeses and fermented milk (Foulquië-Moreno et al., 2006).

Comparison of API with sequencing of 16S rDNA gene

The different methods of evaluation provided different patterns of genera and species identification for the LAB isolates (Table 2). Regarding the results by sequencing of 16S rDNA gene, the only species identified was Enterococcus faecium, whereas API50CHL mostly identified Lactobacillus spp., Lactococcus, Pediococcus. These results were similar to finding of Moreas et al. (2013). Differences between sequencing and phenotypic tests have already been observed previously, not just for LAB but also for many other bacteria (Aymérich et al., 2003; Velasco et al., 2004; Gomes et al., 2008). Despite being the most reliable test, sequencing has some disadvantages. Because it is so conserved, in some cases the 16S rDNA gene is not sufficient for differentiating between species of LAB, especially Enterococcus spp. (Aymérich et al., 2003; Mohania et al., 2008). Considering the difficulties in differentiating between some LAB species with 16S rDNA sequencing and phenotypic tests, the application of specific molecular techniques such as species-specific PCR is necessary. For example, the identification of Enterococcus spp. is based on the detection of the d-alanine-ligase enzyme, antibiotic resistance and specific regions (Dutka-Malen et al., 1995). Species-specific PCR is also useful for identifying microorganisms at subspecies level, which cannot be easily achieved with other common techniques (Beimfohr et al., 1997). Another disadvantage is the time required to obtain the sequencing results, which is considerably higher than the time needed to obtain phenotypic test results.

CONCLUSION

In conclusion, the choice of identification method must be carefully analyzed. Some factors must be considered, the number of isolates to be identified, and staff qualifications. A phenotypic test could be used as a trial test, but the molecular methods are more accurate and should be used as confirmatory tests for hard-to-identify isolates. Considering that most of the LAB isolation and identification studies aim to detect potential bio-preservation isolates from food, the molecular approach is probably the most sensitive.
